**Abstract:** The *Staphylococcus aureus* is often responsible for a number of diseases in humans and animals, and it is considered as a main etiological agent of bovine mastitis. The pathogenicity of *S. aureus* is due to both its ability to resist antibiotics, and the production of toxins. This study investigated virulence genes, prevalence and antibiogram profile of *S. aureus* isolated from dairy cows suffering from mastitis in the Kashmir. A total of 70 *S. aureus* isolates were obtained from 250 mastitic milk samples collected from both organized (47/150) and unorganized (23/100) dairy farms. Five pathogenic factors including clfA, hld, seo, lukM, and coa and one resistance gene mecA were checked through PCR. Clumping factor gene (clfA) was found in most of the isolates with a percentage of 81.42 % whereas, hld, seo, lukM, and coa were present in 61.2, 54.28, 70, and 71 percent of isolates, respectively. However, amplification of coagene yielded DNA bands of two different sizes. A high percentage of antimicrobial resistance rates were observed, wherein, Ampicillin showed highest resistance with 85.7 %, followed by Kanamycin, Cefotaxime, Sulphadizine and Streptomycin showing 71.42 %, 54.28 %, 51.48 % and 42 %, respectively. A high frequency of Methicillin resistant *S. aureus* (MRSA 28.57 %) was observed in these isolates and all mecA resistant isolates were found to be positive for mecA gene via PCR amplification. These results revealed that mastitis-associated *S. aureus* among bovines of Kashmir is able to accumulate different virulence factors and resistance to antimicrobials, making the treatment of infections difficult.

**Keywords:** Antibiogram, Genotypic characterization, Mastitis, PCR, *Staphylococcus aureus*

**INTRODUCTION**

India is the largest milk producer of the world producing 121.8 million tons of milk per annum from 199.1 million cattle and 105.3 million buffaloes which accounts for about 17 per cent of total global production (NDDB, 2012). Despite the high growth rate in production, the average milk yield of cows and buffaloes has remained low. One of the main reasons for low productivity of milk is mastitis, which is single largest problem in dairy animals in terms of economic losses in India. In India overall losses due to mastitis is estimated at Rs. 7165.51 crores (Bansal and Gupta, 2009). It is reported that the annual economic losses due to bovine mastitis has increased 114 folds in about 4 decades from 1962 (INR 529 million/annum) to 2001 (INR 60532 million/annum) (Dua, 2001).

*S. aureus* has a capacity to produce a large number of potential virulence factors, including a variety of exotoxins and cell surface-associated proteins (Kaloyer et al., 2007). The identification of virulence factors is an important step in elucidation of disease process. The pathogenic potential of *S. aureus* depends on numerous cell surface virulence factors and it has capability of producing a variety of exotoxins and cell surface-associated proteins that enhances the cellular attachment, organism invasion to host immune system and stimulation of toxic tissue reactions (Hussain et al., 2012). *S. aureus* secretes various cytotoxins like leukocidins and haemolysins which are responsible for the lesions observed during the development of the infection (Dinges et al., 2000).

In addition to the virulent factors the evolution of antibiotic resistance in *S. aureus* strains is a serious cause of concern in dairy animals (Wang et al., 2008). The *S. aureus* acquires antibiotic resistance with remarkable proficiency (Booth et al., 2001). Strains of *S. aureus* resistant to β-lactam antibiotics are known as methicillin-resistant *S. aureus* (MRSA). These strains in intra-mammary dissemination often produce inurable severe intra-herd infections (Kumar et al., 2010). The MRSA strains have been observed to be multi-drug resistant, especially to aminoglycosides, macrolides, lincosamides, streptogramins, tetracyclines,
which are often used in the treatment of mastitis (Kumar et al., 2010). The transmission of bovine MRSA to humans is possible and may contribute to outbreaks in human populations (Lee, 2003).

The identification and characterization of virulence factors of *S. aureus* causing bovine mastitis will enhance our understanding of the pathogenesis of intramammary infection. In addition, the antibiogram of *S. aureus* needs to be studied which would indicate the pattern of resistance to various antibacterials contributing to their virulence properties. These may in turn contribute to the development of methods to minimize the production losses due to mastitis. Further, the study of evolution of strain-specific transmission and virulence characteristics including antibiotic resistance in *S. aureus* isolated from bovine mastitis may help us to understand mechanisms behind emergence of new strains or shifts in mastitis epidemiology in response to control measures, including antibiotic treatment and vaccination. Keeping in view the above facts the objective of this study was to determine the genotypic characterization and antibiogram of *S. aureus* isolated from milk of cows suffering from mastitis in Kashmir.

**Materials and Methods**

**Sample collection:** A total of 250 mastitic milk samples were collected from organised and unorganized farms in Kashmir. The samples were collected in sterile test tubes and brought to the laboratory on ice in a cool box and processed within two hours of collection.

**Isolation and confirmation:** For isolation, samples were inoculated in nutrient broth and incubated at 37 °C for 24 hr. Enriched samples were streaked on nutrient agar (Himedia) plates and the plates were incubated at 37 °C for 24–48 hr. After incubation suspected colonies were sub cultured on the nutrient agar until they were free from contaminating bacteria. After incubation suspected colonies were sub cultured onto Mannitol salt agar (Himedia) and incubated for 24 to 48 hrs and examined for bacterial growth and typical colour change of media. Isolates were further examined by conventional methods including colony morphology, Gram's staining and biochemical tests to ascertain their identity as *S. aureus*.

DNA isolation: The template DNA was prepared by boiling and snap chill method. Briefly, purified individual colony from Mannitol Salt Agar (Hi-Media, India) was dissolved in 150 µl sterile double distilled water in microcentrifuge tubes. The tubes were kept in water bath set at 100 °C for 10 min and then in crushed ice for 20 min. The tubes were then centrifuged at 10000 g for 5 min and the supernatant collected was used as template. The concentration and purity of the extracted DNA was checked using spectrophotometer and stored at -20 °C until use.

Identification of *S. aureus* by using species specific PCR: The isolates identified by cultural and biochemical methods as *S. aureus* were genetically confirmed by amplification of species specific *mecA* gene by PCR using Forward 5'GGCATTGATGTGATACGGTT3' and Reverse 5'AGCCAAGCCTTGACGAACTAAGC3' primers (Brakstad et al., 1992). The reaction consisted of 2.0 μl template DNA, 2.5 μl of 10X buffer, 0.2 μl of 25mM dNTP mix, 1 U of Taq DNA Polymerase (Fermentas Life Sciences). MgCl₂ was used at 2.0 mM concentration and sterile distilled water. Amplification was carried out with initial denaturation at 94 °C for 5 min, followed by 35 cycles of denaturation at 94 °C for 1 min, annealing at 55 °C for 30 sec, extension at 72 °C for 1 min and final extension at 72 °C for 7 min.

Virulence gene detection: DNA amplification of virulence genes encoding for clumping factor (*clfA*), delta haemolysin (*hld*), leukocidin (*lukM*), enterotoxin O (*seo*), coagulase (*coa*), and methicillin resistance gene (*mecA*) was carried out using PCR. Details of oligonucleotide primers used in the present study are mentioned in Table 1. All the reactions were performed in a final volume of 25 μl of mixture containing 2.5μl of 10X PCR buffer, 2 μl of 25mM MgCl₂, 25 mM of each of dNTP, 20 pmol of each gene-specific primers, 1 U of TaqDNA Polymerase (Fermentas Life Sciences) and 2μl of template. The cyclic conditions for each reaction are given in Table 2. The PCR assays were performed in Gene Amp PCR System 2400 thermal cycler (Applied Biosystems, Foster City, CA, USA).

**Fig. 5.** Agrose gel electrophoresis of PCR amplicon of *clfA*, *hld*, and *seogene* of *S. aureus* isolates. Lane 1: DNA marker, Lane 2: Sample Positive for *hld*gene(236 bp), Lane 3: Sample Positive for *seogene*(300 bp) and Lane 4: Sample positive for *clfAgene*(855 bp).

**RESULTS AND DISCUSSION**

Prevalence of *S. aureus* strains in bovine mastitis: Among 250 samples collected, 70 isolates revealed colonies typical for *S. aureus* which were later confirmed by PCR amplification of the *mecA* gene which produced an amplicon of 270 bp (Fig. 1). The *S. aureus* infection was more prevalent in unorganized farms which accounted to be 31.33 % in contrast to organized farms which accounted for 23 %.

**Virulence genes:** PCR amplification of *clfAgene* resulted in single amplicon of 855 bp for 57 *S. aureus* isolates (Fig. 5). However, in case of *coagene*, 50 sam-
samples were positive and yielded two different products of 910 bp and 730 bp for 38 and 12 isolates respectively (Fig. 4). Amplification of hld gene produced an amplicon of 236 bp in 43 isolates (Fig. 5) and 49 isolates showed an amplicon of 792 bp for lukMgene (Fig. 3). Amplification of seo gene yielded an amplicon of 300 bp for 38 isolates (Fig. 5). A total of 20 out of 70 isolates possessed mecA gene by depecting an amplicon of 310 bp (Fig. 2).

**Antibiogram:** A wide range of susceptibility to antimicrobials was observed among *S. aureus* isolates. Out of the 70 isolates 94.28 % were sensitive to a combination of Amoxicillin and clavulanic acid. This was followed by Chloramphenicol (91.4 %), Vancomycin (88.57 %), Gentamycin (84.2 %), Ceftriaxone (82.8 %), Methicillin (72.85 %), Cephalexin (68 %), Amikacin (61.42 %) Enrofloxacin (60 %), Oxytetracycline (62.8 %). High resistance was recorded against Ampicillin (85.7 %) which was followed by Kanamycin (71.42 %) Cefotaxime (54.28 %) and Sulphadizine (51.48), Streptomycin (42 %). (Fig 6) Twenty isolates were found to be methicillin-resistant, while the remaining (50) were methicillin-susceptible. All the MRSA isolates were positive for mecA gene.

Worldwide, mastitis has been reported to be one of the most common infectious disease affecting dairy cows and the most economically important disease of dairy industry. Since *S. aureus* is the most frequently isolated agent in mastitis cases all over the world, it is important to reveal virulence factors helping in pathogenesis and antimicrobial resistance pattern of the organism to develop effective control strategies against mastitis caused by *S. aureus*. The present study was therefore focused to detect some of the virulence factors and susceptibility pattern of the *S. aureus* isolated from bovine mastitis milk samples in Kashmir province. *S. aureus* are classically identified by conventional methods that are time consuming and expensive and they leave a situation of ambiguity because of variability showed by different strains. More recently, PCR based methods involving amplification of species-specific genes, like nuc gene have been used for identification of *S. aureus*. The nuc gene based PCR has been widely used for identification of *S. aureus*. Yamagishiet al. (2007) and Kuzma et al. (2003) have used nuc gene amplification as a tool for the identification of *S. aureus* in mastitic milk.

In the present study seventy samples were positive for *S. aureus*, indicating an occurrence of 28 % bovine mastitis in Kashmir Valley. Ranjan et al. (2011) has reported occurrence of 27.37 % for *S. aureus* from bovine mastitis in Jharkhand, India and Botrel et al. (2010) has reported a prevalence of 30.2 % for *S. aureus* from clinical and subclinical mastitic dairy cows in Rhone-Alpes, France. The reports suggest high prevalence pattern of *S. aureus* in bovine mastitic milk in India and abroad.

The binding of an organism to the host cell is an important factor for pathogenesis. The ability of *S. aureus* to adhere to extracellular matrix proteins is thought to be essential for colonization and establishment of infections (El.sayed et al., 2005). Presence of 57 positive clfA samples indicates probable important role of these elements in the pathogenicity of bovine mastitis. Similarly, more than 50 % of the isolates studied were positive forlukM gene which is highly cytotoxic on bovine neutrophils (Barrio et al., 2006). It’s a family of pore-forming toxins which may be involved with escape from the phagosome after phagocytosis and intracellular survival, which is an important trait for the maintenance of *S. aureus* intramammary infection (Degi et al., 2002).

In the present study, screening of *S. aureus* isolates for the presence of coa virulence gene has revealed that 50 of the 70 (71.4 %) isolates carried the gene. All the positive isolates showed a single amplicon but of two different sizes, 970 bp and 730 bp. This finding is in agreement with that of Momtaz et al. (2011), who carried out coa gene amplification from bovine mastitic samples. From 86 *S. aureus* isolates, they found 31 isolates to amplify 970 bp fragment, and 11 isolates to amplify 730 bp through PCR amplification. Analysis of coagulase-encoding *Staphylococcus aureus* DNA...
(coa) genes has demonstrated variable sequences in the 32-end coding region. This region contains a polymorphic repeat region that can be used to differentiate *S. aureus* isolates (Guler et al., 2005).

During the progression of infection, *S. aureus* can produce superantigenic toxins including staphylococcal enterotoxins (SEs), their interest reside not only in their potential role in staphylococcal diseases by modulating the host immune response contributing to maintain a suitable environment for colonization (Omoe et al., 2002) but also in their ability to cause food poisoning. The fact that 38 isolates (54.28 %) in this study harbored this super antigenic gene suggests that mastitis due to *S. aureus* might represent a risk for human health due to presence of these enterotoxins in milk.

In the present investigation, 61 % of the isolates possessed *hld* gene. Contrary to this in Finland and Spain, Haveri et al., (2007) and Fuego et al., (2005) found *hld* gene present in 88.8 % and 84 % of *S. aureus* isolates of bovine mastitis, respectively. Delta haemolysin is recognized to have detergent action on cell membranes resulting in cell lysis (Marconi et al., 2005).

Emergence of antimicrobial resistance among animal pathogens is of growing concern in veterinary medicine as it renders antimicrobials ineffective for treating the animals. In addition, the antimicrobial resistance in zoonotic pathogens, like *S. aureus* possess a potential risk for human health too. In Methicillin resistant *S. aureus* (MRSA), the resistance to antibiotics is caused by an altered penicillin-binding protein, which makes it resistant to all β-lactam antimicrobials. The *mecA* gene encodes for this protein and is therefore widely used to identify MRSA. *S. aureus* isolates were screened for *mecA* gene by PCR and it was found that 28.57 % were positive for the gene. All the isolates which were positive for *mecA* gene were phenotypically resistant to methicillin, whereas sensitive and intermediate sensitive isolates for methicillin were devoid of the *mecA* gene.

The antibiogram profile in the present study indicated that Amoxicillin with Clavunid acid, Chloramphenicol, Vancomycin, Gentamycin, were most effective antimicrobials, whereas Ampicillin, Kanamycin, Cefotaxime, Sulphadizine and Streptomycin was least effective against *S. aureus*. Majority of investigators have presented different results, but some agreement has also been found with present study Turutoglu et al. (2006) and Malinowski et al. (2008) reported 97.4 % and 93.2 % of *S. aureus* isolates sensitive to amoxicillin and clavulanic acid, respectively. Li et al. (2009) and Khakpoor et al. (2011) recorded maximum resistance to ampicillin in *S. aureus* isolates from bovine mastitis. The long indiscriminate use of Ampicillin would have been responsible for development of resistance towards this antibiotic (Gitau et al., 2011) whereas the Amoxicillin with Clauvinic acid antibiotic is relatively less used for treating mastitis (Horodyska et al., 2012) and thus most effective. The regular monitoring of antimicrobial susceptibility of *S. aureus* will not only result in the use of right antibiotic for control of *S. aureus* infections but will also help in avoiding the development of multiple drug resistant strains of *S. aureus*. Same is also true for all other microbes involved in various diseases and infections in humans and animals.

**Conclusion**

To our knowledge, this is the first report of genotypic characterization and antibiogram in *Staphylococcus aureus* strains isolated from bovine mastitis in Kashmir. Parameters of this study suggest that there is a broad distribution of closely related *S. aureus* clones which are responsible for the mastitis situation in Kashmir. Difference found in the gene patterns and antibiogram provided a better understanding of the distribution of the prevalent *S. aureus* clones among bovine mastitis isolates. Therefore, determining the virulence gene profile and antibiogram of *S. aureus* isolates from bovine mastitis will be helpful in devising strategies for therapeutic intervention and control of mastitis.
