Abstract: A field experiment was conducted during the year 2011-13 to study the nutrient management based on soil test to achieve the target yield of jute and rice and their effect of soil nutrient status for jute-rice cropping system. The target yield of jute fibre (3.5 t/ha) with -6% deviation and target yield of rice (5.5 t/ha) were achieved with application of 100% NPK based on ST-TY based along with 5 t/ha Farm Yard Manure (FYM). The highest system productivity (11.7 t/ha) and benefit-cost ratio (3.16) was also recorded higher with application 100% NPK based on ST-TY based along with 5 t/ha FYM. The nutrient uptake by crops and soil nutrients status were higher after three year of jute-rice cropping sequence when NPK were applied with FYM. Hence, combination of inorganic and organic (FYM) fertilizer could achieve target yield and maintain the soil fertility status.

INTRODUCTION

Balanced fertilizer application in a cropping system is pre-requisite for sustainable production system as well as appropriate soil nutrient resilience. With the development of high yielding and fertilizer responsive varieties of almost all crops escalated the indiscriminate use of fertilizers thus increases cost of cultivation and environment pollution. Hence, need based estimation of N, P and K correlating their requirement with specific target yield depending on their native soil status may fit to balanced application of NPK fertilizers. The 'target yield equation' (TYE) is considered as a soil and fertilizer based precision farming strategy to meet nutrient demands for a specified yield (Balasubramanian *et al.*, 1999). However, application of N,P and K fertilizer on soil test target yield (ST-TY) based may meet the productivity but it has negative impact on soil health, hence, integrated nutrient management *i.e.* combination of inorganic and organic in jute-rice cropping system help to enhance the jute and rice productivity while maintaining the soil health (Ghosh, 2008). Keeping this view in mind the experiment was conducted to achieve the target yield of jute and rice and their effect of soil nutrient status for jute-rice cropping system

MATERIALS AND METHODS

The experiment was conducted at Crop Research Station, Bahraich in jute-rice system during 2011-13. The soil of experimental field was sandy loam with pH 7.5,

organic carbon 0.24 % and available N, P and K 215, 22.5 and 125 kg/ha, respectively. Doses of N, P₂O₅ and K₂O calculated on soil test basis by using following equations:

For jute (Singh *et al.*, 2012)

$$FN=8.03T-0.45 SN$$

$$FP=1.49T-0.27 SP$$

$$FK=2.77T-0.19 SK$$

For rice (Ray *et al.*, 2000)

$$FN=5.29T-0.39 SN$$

$$FP= 1.03T-0.24 SP$$

$$FK=1.98T-0.20 SK$$

Where, T= Yield target; FN, FP and FK is fertilizer N, P₂O₅ and K₂O(kg/ha), respectively;

SN,SP and SK are available N P and K of soil (kg/ha), respectively.

Seven nutrient management practices viz. T₁- Control, T₂- Recommended dose of jute fertilizer (RDF) *i.e.* for jute 60 kg N, 30 kg P₂O₅ and 30 kg K₂O/ha and for rice 150 kg N, 60 kg P₂O₅ and 60 kg K₂O /ha , T₃ - RDF + Farm yard manure (FYM), T₄- 100 % NPK on ST-TY (Target for Jute -3.5 t/ha and for rice- 5.5 t/ha), T₅-100 % NPK on ST-TY (Target for jute -4.0 t/ha and for rice 6.5 t/ha), T₆- T₄ + 5 t /ha of FYM and T₇ - T₅ + 5 t/ha FYM were tested in randomized block design with three replications for jute and rice. Jute variety 'JRC-212' was sown in the first week of April and rice variety 'NDR 62' was transplanted in 2nd week of July in every year with recommended package and practices. The fibre yield in jute crop and grain yield of rice crop was recorded after harvesting of crop. Soil and plant samples were collected at harvest were

dried, processed and analyzed for available N by alkaline permanganate method, available P by Olsen's method and available K by flame photometer following standard procedures (Jackson, 1973). The economics in term of benefit cost ratio was also calculated at price prevailing in nearest market. The fibre yield of jute, grain yield of rice, and other parameters of nutrient dynamics were subjected to standard analysis of variance (ANOVA) and treatment differences were tested following tests of least significant difference (LSD) at statistical significance level of $P \leq 0.05$ (Gomez and Gomez, 1984).

RESULTS AND DISCUSSION

Fibre yield, rice yield and system productivity: The target yield of jute (3.5 t/ha) was achieved with -6% deviation (Table 1) with application of 100%NPK based on Soil Test Target Yield (ST-TY) equation along with 5t/ha of FYM (T₆). The 100% NPK application on ST-TY achieved only 84.5 % of target jute fibre yield. The higher jute fibre target yield (4.0 t/ha) could not be achieved by any treatments. The target yield of rice (5.5 t/ha) was also achieved with T₆. The higher target yield(6.5 t/ha) of rice could not be achieved by any treatments, however, 100% NPK based on ST-TY

along with 5 t/ha of FYM was achieved 89.5% of this target yield. The integration of inorganic with organic (FYM) was ensured the achievement of target yield of jute and rice and only inorganic (N, P and K) did not achieve the target yield in both jute and rice. Balanced nutrition to soil, through integration of both organic and chemical nutrient sources appears to be essential. It provides adequate nutrients to crop uptake which promotes jute and rice growth and subsequent development of yield attributes lead to higher yield (Ghosh, 2008; Guha, *et al.*, 2008). Target yield was not achieved exactly, showing a slight deviation from the grain yield which might be due to unavailability of the full amount of applied nutrients to the plant as estimated to achieve the targeted yield. One possibility is that release of nutrients from applied fertilizer occurs spontaneously; however, subsequent uptake by plant is not taking place concurrently. Thus, entire amount of applied fertilizers could not have been up taken due to lack of synchronization of its release with its absorption by plant, accounting for uncontrollable losses (Balasubramanian *et al.*, 2003). The system productivity and benefit cost ratio was significantly ($P \leq 0.05$) higher in T₆ and T₇, where FYM was integrated

Table 1. Jute fibre yield, rice yield, percent achievement of target yield, system productivity and benefit-cost ratio under jute-rice cropping system (pooled data of 2011 to 2013).

Treatments	Fibre yield (t/ha)	% achievement of jute fibre target yield	Rice yield	% achievement of rice target yield	System productivity (t/ha)	B:C

with ST-TY based application of NPK compared to T₁, T₂ and T₃ treatments (Table 1). The combination of inorganic and organic resulted in higher productivity of jute/mesta and rice was also reported by Ray, *et al.* (2000) in jute-rice -wheat cropping system, Saha, *et al.* (2008) in roselle; Kumar, *et al.* (2010) in jute and Singh, *et al.* (2011) in mesta-rice cropping system.

Nutrients uptake and its status in soil: The higher nutrient uptake (94.9 N, 37.7 P and 105.5 K kg/ha) by jute and (117.3 N, 68.8 P and 91.1 K kg/ha) by rice crop were recorded under T₇ and which was found significantly ($P \leq 0.05$) superior than other treatments (Table 2). The higher uptake of nutrients under T₇ which might be due to higher application of nutrients along with FYM. Available nutrient status was also higher in T₆ and T₇ where FYM was applied. When we apply FYM in soil the entire amount of its NPK constituent was not made available at a time in one season; rather, a gradual release took place over a period of years. It has been reported that only 25% to 30% N, 60% to 70% P, and 75% K could be made available from applied FYM in first season rice, and the remainder being available in subsequent years (Gaur *et al.*, 1984). Hence, comparatively less yield deviation under integrated nutrient management was attributed to slow but sustained release of nutrients and due to improvement in humic substances in soil, which in turn promotes the soil NPK status.

Conclusion

The present study concluded that the application of N, P and K based on STCR equation with 5 t/ha FYM achieved target yield of jute fibre ($\sim 3.5 \pm 0.2$ t/ha) and rice (5 t/ha) and recorded higher system productivity

and benefit-cost ratio. It also maintained the soil fertility status of soil in jute-rice cropping system
